Building Context Aware P2P Systems
with the Shark framework

Thomas Schwotzer

FHTW Berlin (University of Applied Sciences)
thomas.schwotzer@fhtw-berlin.de

Abstract. Abstract: Shark Framework is framework supporting implementation of context aware P2P systems. Shark is an acronym and stand for Shared Knowledge. There is already a theory on context aware P2P systems which is implemented by the Shark framework. Target platforms are in the first step J2SE, J2ME and Android. In next steps iPhone and Microsoft based mobile devices will be supported. Shark FW supports the Knowledge Exchange Protocol (KEP) which is a stateless P2P protocol. Currently KEP has been ported to UDP and TCP. A Bluetooth L2CAP implementation will be available in October. This paper (briefly) explains core concepts of the framework. Sample code illustrates usage of Shark. It is illustrated that just two lines of code are sufficient to set up a peer that exchanges knowledge. This paper is also a call for participation. Shark is an open source project and is open to developers and users.

1 Introduction

Knowledge management is an inherently distributed process. Knowledge is not created in a company, a think tank or whatever. Knowledge is initially created in an individual's mind. Usually people decide to share knowledge. Such newly created knowledge will usually be discussed in groups. It will be exchanged, combined, modified and maybe forgotten. Knowledge always flows within and between groups and between individuals. Groups can be official organizations, e.g. companies but also ad hoc groups or other not official networks of people.

Knowledge management systems (KMS) must support knowledge sharing. Topic maps is a knowledge representation standard. It supports knowledge sharing. The standardized merge operation defines how knowledge from different sources can
be integrated. The topic map query language but also the topic maps API can be used to take parts (fragments) from topic maps. Such fragments can be exchanged between topic maps. There are some examples of distributed topic maps applications.

Thus, there are means to combine knowledge but also to take parts of knowledge out of an existing knowledge base that is based on topic maps. Developers of distributed knowledge management systems (more specific: distributed topic maps systems) need additional functionality. A protocol for knowledge exchange is required and applications must decide if and what parts of knowledge are allowed to be exchanged. Currently, this functionality must be completely implemented within the application. Of course, there is no need to implement any marshalling / serialization code line by line. Middleware systems, Web services etc. pp. can be used. Nevertheless, the whole exchange logic is application specific.

The Shark framework is an open source project. It provides a stateless P2P protocol called KEP (Knowledge Exchange Protocol) and an API for building distributed P2P applications. Shark is independent from a specific knowledge representation format. The Shark concept has its roots in topic maps and therefore most core concepts and ideas are inspired by and compliant to topic maps. A core concept of Shark is the Knowledge Port (KP). A KP can be compared to a TCP or UDP port. It is – hopefully – as easy to define and to open as a socket in e.g. Java. Knowledge ports exchange knowledge particles (more specific: topic map fragments if topic maps engines are used). KPs contain the KEP protocol engine and form the interface between the P2P protocol and the used knowledge base.

The aim of this paper is twofold. First, the Shark framework shall be introduced. It will be shown that an useful P2P communication can already be defined by just a few lines of code.

Secondly, it is a call for participation. There is already a theory on Shark, see e.g. [SG02][MS05] and referenced papers. The Shark framework is new though. Currently it is written in Java and runs with J2SE and J2ME and supports UDP and Bluetooth L2CAP. There are only a few applications yet. Shark will be ported to compact .NET, Android and maybe to iPhone. The source code is available from sourceforge [SharkFW].
2 Building Distributed Applications with XTM, TMQL, TMAPI etc.

Topic maps comprise a whole family of formats and languages. Some of them are standardized. The ISO topic maps standard [TM] describes the data model and its semantics. It is the basis of the following formats and standards. XTM [XTM] is a XML schema for topic map representation. It is part of [TM]. The topic map query language [TMQL] is used to retrieve parts (fragments) of a topic map based on a query. Finally, TMAPI is an (not standardized) API for the management of topic maps. We have everything what's required to implement a topic maps application. The following figure illustrates the relationship between the components of a distributed TM application.

The application specific code is on top of the diagram. It uses TMAPI or TMQL to access and manipulate the underlying topic map(s). The topic map itself is stored in a component that is called Knowledge Base. There are no constraints on how topic maps are actually stored. The TMAPI and TMQL implementions hide KB specifics from TM applications and its developers.

![Fig. 1. Components of a Distributed topic maps Application](image)

There is no explicit support for building distributed applications with topic maps. Application developers are free to use arbitrary network protocols to e.g. exchange topic maps with XTM or TMQL queries and their results. The communication issues are implemented in the application itself. Thus, it is an application specific protocol that enables communication between remote topic maps engines. TMShare [TMShare] is an example of such a distributed topic maps application.
P2P applications are a special class of distributed applications. There is no common definition of peers. In [Sc08] a model of autonomous context-aware peers is proposed – the ACP model. The basic ideas of the model are straightforward. Peers have the following features:

- A peer has its own knowledge base. There are no constraints on the knowledge representation formats used by the knowledge base. Of course, in this context a knowledge base can be assumed to be a topic maps engine.
- A peer observes its environment. Changes of the environmental context are recognized and can lead to an activity, e.g. the delivery of a message or the change of an internal status.
- A peer can send messages to other peers in its environment. The definition of environment remains very vague in the ACP model. It can be a local area network but also the WWW.
- Peers have (not necessarily unique) identifiers.
- Peers are autonomous. They can autonomously decide under which circumstances (based on the current environmental context, current connections to other peers, already exchanged messages, status of the knowledge base etc. pp.) messages are sent to other peers and what information are delivered.

Whenever peers take notice of each other they can decide to exchange messages and finally to exchange knowledge. Two processes have to be distinguished. Knowledge extraction is the process of taking knowledge from a peers knowledge base in order to send it to a remote peer. Knowledge assimilation is the process of retrieving knowledge and (partially) integrating it in the local knowledge base.

More formal, both processes can be defined as functions (in a Java like syntax):

```java
Knowledge extraction(recipients, environmental context, status);

void assimilation(sender, environmental context, status, knowledge);
```

Extraction generates a knowledge particle (in this context a topic map fragment). Extraction is influenced by the identity of the potential recipient, the current environmental context and the status of the peer. Assimilation integrates (parts of)
the retrieved knowledge. This process is influenced by the sender's identity (if known), the current environment and the internal status.

There are, deliberately, no algorithms defined for any of the functions in ACP. This is up to an ACP implementation. The simplest implementation of assimilation is a topic map merge. The easiest implementation of extraction would be the usage of a static TMQL query. Both implementations would ignore the environment and the identity of the potential communication partners and would lead to a kind of distributed topic map but not to a network of autonomous context aware peers.

4 Shark framework – an implementation of ACP

The Shark framework [SharkFW] is an implementation of the ACP model. This supports the implementation of autonomous peers which can exchange knowledge in the described manner. The framework is written in Java and is currently available for J2SE and J2ME. The launch of version 1.0 is scheduled for September 2008. It is an extensible open framework with only a few requirements for underlying knowledge bases and communication environments used. A knowledge base must implement the functions extract and assimilate. An environment must allow the sending and retrieving of messages and should optionally be able to recognize changes (e.g. the appearance of a peer). Version 1.0 comprises an UDP-Environment, a topic map with J2SE, a Bluetooth-Environment and a very simple knowledge base based on J2ME.

The main features of the Shark core are an API for autonomous peers and the implementation of a protocol engine supporting the P2P Knowledge Exchange Protocol (KEP).

5 Knowledge Exchange Protocol (KEP)

KEP is the Shark specific P2P protocol. There are four KEP commands. KEP was influenced by software agent protocols [KQML], [ACL]. In the following the four KEP commands will be briefly described.

- The interest command is submitted by a peer to indicate its retrieving interest. A peer can define what kind of information it is willing to receive. In Shark, this definition is simply done by naming a number of topics. Of course, XTM or LTM are preferred representation formats.
The offer command is submitted by a peer to indicate its sending interest. A sending interest is the counterpart of a retrieving interest. A peer describes the kinds of information it is willing to send.

The accept command is similar to the interest command but with slightly different semantic. Accept delivers a retrieving interest. The sender of an accept command expects to get a knowledge particle in reply (in return?).

The insert command submits a knowledge particle, e.g., a XTM document. A sender will extract a fragment from its local knowledge base and send it to one or more recipients using a KEP insert command. The recipients will assimilate the retrieved knowledge. Both, extraction and assimilation algorithms are application (class) specific.

KEP is a stateless protocol. There is not even an implicit defined order of commands. Thus, KEP can easily be implemented with UDP, Bluetooth L2CAP and other datagram protocols.

Each KEP command contains the name of the sender (or anonymous) and the names of the potential recipients (or anonymous). There are some common usages of KEP sessions.

6 KEP scenarios – Internet peers

In the first scenario it is assumed that two peers with huge knowledge bases can establish a stable communication channel e.g. a TCP based connection in the fixed Internet. In the first step both peers can negotiate a mutual interest. This can be done by an exchange of interest/offer messages.

An example will explain the approach. Peer A has information about the latest music bands and movies. Peer B may be interested just in music. Thus, A would describe its sending interest with music, movies. (Note, this is an abbreviation. Music should be read as e.g. a topic standing for the concept of music. The string music can be a basename of this topic.). B would describe its retrieving interest with music. Now, A could send an offer(music, movies) command to B or B could send an interest(music) command to A.

If A receives (?) an interest(music) it can decide if and what to offer to B. In this example it would probably send an offer(music) to B. If B would receive (?) an offer(music, movies) from A it would learn that A has information on music and would probably reply with interest(music). At the end of both sequences, B
knows that A offers music information. A knows that B is interested in music. Music is of mutual interest.

Now, B could send accept(music) to A. A would extract music information and send insert(musicKnowledge) back to B. Alternatively, A wouldn't wait for an accept and directly send an insert command.

![Fig. 2. Knowledge Exchange with Shark's Knowledge Ports](image)

### 7 KEP scenario – Peers in spontaneous networks

Spontaneous networks are networks of mobile nodes which tend to enter and leave a network frequently. Moreover, a peer that was in a spontaneous network cannot be assumed to enter it again. A knowledge exchange strategy must be adopted to these characteristics.

A spontaneous network could e.g. be a network of two Bluetooth applications e.g. running on mobile phones. It takes several seconds to establish a connection. Bluetooth mobile phones can usually communicate within a radius of 10 m. Imagine two pedestrians (~ 3 km/hour and their mobile phones in their jackets) would pass each other. As soon as the distance is smaller than 10 m a spontaneous network could be established. The BT channel is of course dropped as soon as the distance is over 10 m again. In this example, both mobile peers would have 12 seconds to establish a connection and to exchange information. Establishing a BT connection can already take about 10 seconds. Therefore there is no time left(?) for lengthy negotiations.

Another strategy should be used: Whenever a peer “sees” another peer in a mobile environment it should try to send relevant information as fast as possible. It could either send a (small) knowledge particle or an (retrieving or sending) interest with a different (e.g. IP or E-Mail) address for replies.
With the first strategy mobile peers would frequently get unsolicited insert commands. They would examine these knowledge particles and maybe assimilate parts of them.

With the second strategy mobile peers would just exchange their interests along with addresses to longer lasting peers i.e. internet peers. Such strategy is useful in environments which combine mobile and fixed peers.

8 Peer API / Knowledge Ports

The Shark framework supports the development of KEP based P2P systems. The following example code illustrates how a peer providing music information can be created.

```java
Peer p = new Peer();

p.getKnowledgeBase().
    addKnowledge("music","new album from madonna", "music news");

KP okp = p.createOKP("music");
okp.setVisible();
```

The first line creates a peer. New information is added to the knowledge base in the second line. Information consists of three parts: topic (“music”), creator (“music news”) and the information itself (“new album from madonna”). Note, this is also just an example and illustrates knowledge base access by Shark. If a topic map engine is used the code could be changed like this:

```java
topic map tm = (topic map) p.getKnowledgeBase();
// do TM specific things, e.g. based on TMAPI or TMQL
```

The third line creates a knowledge port (KP). There are two knowledge port classes: incoming and outgoing knowledge port (IKP / OKP). An IKP is an object representing a set of information for assimilating information(?). An OKP is an object holding information for an extraction process. The function above is just a convenience function. The general KP constructor is defined as follows:

```java
KP(KnowledgeBase kb, Peer peer, Context ctx, Context interest, PeerName peers, boolean ikp, boolean okp)
```

The kb is the knowledge base which will extract or assimilate knowledge. The peer is the sending peer, ctx describes requirements for the environment, interest is either a sending or a receiving interest and peers describes the names of
potential communication partners of this port. Finally, two boolean values allow to define a knowledge port as IKP or OKP or both.

The convenience function in line 3 actually creates an OKP using the main knowledge base of the calling peer. The calling peer being the sender, defines no constraints on an environmental context. It defines just a single topic as interest ("music") and allows to communicate with any peer that will be detected.

The last line makes this newly created OKP visible. Depending on the used environment, the KP will e.g. be published in a service directory and/or a broadcast is sent into the spontaneous network etc. pp.

Defining an IKP is as simple as defining an OKP:

```java
Peer p = new Peer();
KP ikp = p.createIKP("music");
```

Both peers will be ready to exchange knowledge after both code fragments have been executed. A KEP protocol session will be performed whenever both peers can establish a communication channel. Knowledge will be exchanged if mutual interests can be negotiated.

As described above there are several KEP strategies. In version 1 just two are supported. Both have been described above. Default is the full negotiation. The KEP strategy of a knowledge port can be changed with the following command.

```java
void kp.setStrategy();
```

9 Shark Engine

The Shark framework is an additional layer above a knowledge base, e.g. a topic maps engine and the application code. It provides a P2P protocol which is designed for loosely coupled systems, namely spontaneous networks but which also works on top of UDP or TCP in IP based networks.

The example above illustrated that e.g. four lines of code are sufficient to create a peer, enter sample data and to open a port for knowledge exchange. Just two lines of code are needed to define a peer that is interested in getting information about music. Shark hides the P2P communication protocol as well as the process of establishing a communication channel to other peers.
The figure above also illustrates a feature of most frameworks for distributed systems. Shark framework already provides a protocol. The application code does not have to deal with protocol specific issues. It only has to define rules for knowledge exchange.

Application independent protocols are an advantage in general; an application specific protocol might potentially change whenever the application is changed. A Shark application isn't even able to change the KEP protocol at all. It can only handle received knowledge or interests in different ways.

10 Shark peers versus software agents

Shark peers have something in common with software agents which are used in the field of distributed artificial intelligence. Nevertheless, there are major differences: Software agents are meant to be entities that can fully replace human users in a dedicated application domain. Agents can simulate plans, strategies of human users as well as (in a reduced and limited manner) feelings and biases.

Shark peers are just containers holding information and algorithms for knowledge exchange. Shark peers are parametrized and run on behalf of human users but they would and could never be seen as a substitute of a human user. From a very abstract perspective Shark peers can be compared to an intelligent filtering system but not to a replacement of personal strategies.
11 Shark peers versus distributed systems

A P2P system is a distributed system. A system based on Shark is a distributed system as well. The concept of autonomy makes it different from e.g. file exchange systems and music exchange platforms. A Shark peer decides (based on its algorithms) if and what kind of information shall be exchanged. In other P2P systems users browse through a collection of information and decide i.e. what to download. Peers are passive entities that make their local information bases accessible to remote peers.

There are distributed systems that hide distribution. Distributed databases combine several databases and present them as a single virtual database to software developers and users. The distribution is hidden. Middleware systems like CORBA, EJB etc. also hide distribution. Shark doesn't. Developers and users are aware of the fact of distribution. Thus, Shark can and should only be used for applications which are not meant to hide the fact of distribution.

12 Summary and outlook

The Shark framework is an implementation of the model of autonomous context aware peers. It is an open framework. The Shark core has just very weak assumptions on knowledge base features. The Shark protocol KEP is stateless and can easily be implemented on top of datagram protocols like UDP and Bluetooth L2CAP. Currently, Shark is implemented in Java (J2SE and J2ME). Nevertheless, Shark is far from being finished. Even version 1.0 can only be seen as a very first step.

Mobile P2P systems should support a broad range of hard- and software. In the next steps Shark will be ported to Google's Android and to Apple's iPhone. Furthermore, applications are needed to prove the concept and to give input for further revisions of the framework. This paper shall also be understood as a call for participation. Shark is published under the LGPL on sourceforge. Shark is an acronym. It stands for Shared Knowledge. Let's share Shark!
